Influenza (The Flu)

Influenza (or the flu) is a highly contagious, acute viral infection that spreads easily from person to person. Influenza is most often caused by type A or B influenza viruses that infect the upper airways and lungs.

Flu season in Queensland is typically from June to September, with a peak usually in August. In the tropical areas the pattern can be more variable and may include clusters outside this period. In 2019, there was a wider distribution of influenza onset in Queensland between March and October, with the peak occurring in August.

Flu is not the same as a common cold, and can be a serious illness. For some people, such as young children, the elderly and those with underlying medical conditions, the flu can cause serious complications requiring hospitalisation and can sometimes lead to death.

Signs and Symptoms:

Symptoms usually appear 1 to 3 days after becoming infected. People are potentially infectious to others even before they have symptoms.

The symptoms of flu can include:

- fever
- sore throat
- dry cough
- headache
- muscle and joint pain
- tiredness or extreme exhaustion

In the elderly, fever may be absent and the only signs and symptoms of flu may be:

- confusion
- shortness of breath
- worsening of a chronic condition

Children are more likely to have gastrointestinal symptoms (nausea, vomiting and diarrhoea).

Treatment:

Generally, flu is managed by:

- resting in bed
- drinking plenty of fluids (particularly water)
- taking over-the-counter medication to help relieve symptoms (take as directed in the product information).
Prescription antiviral medications can reduce the length of time symptoms last and help you return to your daily routines earlier. These medications are most effective if they are started within 48 hours of flu symptoms appearing.

See your doctor or call 13 HEALTH (13 43 25 84) if you:
- are concerned about your symptoms
- are in a high-risk group and have a cough and or high fever (38 degrees Celsius or more) that is not improving

Health outcome

Most people recover from the flu within a week, although a cough and tiredness may persist.

Serious complications of flu occur in a small proportion of people who are infected and include pneumonia, inflammation of the heart muscle and neurologic complications, which can lead to hospitalisation and death. People at highest risk of complications from flu include those with pre-existing medical conditions. However, previously healthy people can also have severe complications.

For young children and the elderly, flu is one of the most common vaccine preventable causes of hospitalisation.

Transmission:

Flu can spread from person to person by:
- droplets spreading from an infected person when they cough, sneeze or talk
- touching surfaces contaminated by infected droplets (including hands, remote controls, phones, keyboards and door handles) and then touching your mouth, nose, or eyes.

People with flu can be infectious to others from 24 hours before symptoms start until a week after the start of symptoms. Children and those who have compromised immune systems can be infectious for longer. Even people with mild flu illness can transmit the infection.

Prevention:

You can reduce the risk of infection by getting vaccinated and practising good hand and respiratory hygiene to protect yourself and others:
- stay home when you are sick (in general, you can be infectious for up to a week after the onset of symptoms)
- wash your hands regularly with soap and water or use an alcohol-based hand rub
- wash your hands before touching your eyes, nose, and mouth
- use a tissue, or the inside of your arm, when you cough and sneeze
- throw tissues away immediately and wash your hands
- don’t share items such as cigarettes, cups, lipstick, toys, or anything which has come into contact with the mouth or nose
- stay at least 1 metre away from people who have flu-like symptoms
- clean frequently touched surfaces regularly, such as mobile phones, keyboards, remote controls, door handles, taps, tables, benches, gym equipment and fridge doors (flu viruses can be removed using household detergent)

Vaccination

Vaccination is the best way to reduce the risk of getting flu. Being vaccinated gives you protection against flu by building immunity to the virus and preventing transmission of the virus to other people.

Vaccination is required annually, as immunity from the vaccine decreases over time and the vaccine can change each year to cover the current virus strains. Vaccination usually takes up to 2 weeks to be effective.

In Queensland, the flu season generally occurs in the southern and central areas of the state between June and September annually, with a peak in August. In the tropical areas the pattern can be more variable and may include clusters outside this period.

Vaccination is recommended for anyone aged 6 months and older who wishes to protect themselves from influenza and its complications.

Free vaccine is available for those individuals at greatest risk of severe flu. They are:
- all children aged 6 months to less than 5 years of age
- pregnant women at any stage of pregnancy
- persons 65 years of age or older
- all Aboriginal and Torres Strait Islander people 6 months and older
- individuals aged 6 months and older with medical conditions which increase their risk of severe influenza and its complications.

All other Queenslanders can purchase the vaccine from their doctor or immunisation provider.
your doctor or local immunisation provider
community pharmacies may offer a flu vaccination service for Queenslanders aged 10 years and older
some local councils may run immunisation clinics
some employers may offer free flu vaccinations for their staff.

The vaccine does not contain live flu viruses and cannot cause flu. However, some people may experience mild flu-like symptoms for up to 48 hours as their immune system responds to the vaccine. Serious reactions to the vaccine are rare. While some people may experience mild side effects such as pain, swelling, and redness at the injection site, these usually resolve quickly.

Immediate allergic reactions to flu vaccine are rare. People who are allergic to eggs are no longer excluded from flu vaccinations and should discuss their egg allergy and vaccination with their doctor.

2020 seasonal flu vaccine

The 2020 seasonal vaccines for the southern hemisphere include the following strains:

- an A/Brisbane/02/2018 (H1N1)pdm09-like virus
- an A/South Australia/34/2019 (H3N2)-like virus
- a B/Washington/02/2019-like (B/Victoria lineage) virus
- a B/Phuket/3073/2013-like (B/Yamagata lineage) virus.

In 2020, all funded vaccines will include all four influenza strains (quadrivalent) and be available for:

- all children from 6 months to less than 5 years of age
- pregnant women (at any stage of pregnancy)
- all Aboriginal and Torres Strait Islander people aged 6 months and older
- all individuals aged 6 months and older with medical conditions which increase their risk of severe influenza and its complications.
- individuals 65 years and older.

Health outcome:

Most people recover from the flu within a week, although a cough and tiredness may persist.

Serious complications of flu occur in a small proportion of people who are infected and include pneumonia, inflammation of the heart muscle and neurologic complications, which can lead to hospitalisation and death. People at highest risk of complications from flu include those with pre-existing medical conditions. However, previously healthy people can also have severe complications.

For young children and the elderly, flu is one of the most common vaccine preventable causes of hospitalisation.

COVID 19 and Influenza

There are currently no vaccines that protect against COVID 19.

Whilst influenza vaccine will not prevent coronavirus infection it can reduce the severity and spread of influenza, which may make a person more susceptible to other respiratory illnesses like coronavirus.
